1 Full conditionals

Introduce the latent variable $S_i \in \{1, \ldots, k\}$, for $i = 1, \ldots, n$, denoting the multiscale level used by the ith subject. Assuming data are normalized prior to analysis, we let $\mu \sim \mathcal{N}(0, I)$ and $\sigma = \mathcal{IG}(a, b)$ for the means and variances of the dictionary densities. Let n_{B_j} be the number of observations allocated to node B_j . Each Gibbs sampler iteration can be summarized in the following steps.

1. Update S_i by sampling from the multinomial full conditional with
$$\Pr(S_i = j \mid -) = \frac{\pi_{B_j(x_i)} f_{B_j(x_i)}(y_i)}{\sum_{h=1}^{k} \pi_{B_h(x_i)} f_{B_h(x_i)}(y_i)}$$
2. Update stick-breaking random variable $V_{B_j(x_i)}$, for $j = 1, \ldots, k$ and $i = 1, \ldots, n$, from Beta(β_p, α_p) with $\beta_p = 1 + n_{B_j}$ and $\alpha_p = \alpha + \sum_{B_h(x_i) \in de\{B_j(x_i)\}} n_{B_h(x_i)}$.
3. Update $(\mu_{B_j(x_i)}, \sigma_{B_j(x_i)})$ by sampling from
$$\mu_{B_j} \sim \mathcal{N}\left(\bar{y}_{B_j} n_{B_j}/\sigma_{B_j}, (1 + n_{B_j}/\sigma_{B_j})^{-1}\right)$$
$$\sigma_{B_j} \sim \mathcal{IG}\left(a_\sigma, b + 0.5 \sum_{\{i: S_i = j, x_i \in B_j\}} \left(y_i - \mu_{B_j}\right)^2\right)$$
with $a_\sigma = a + n_{B_j}/2$, $\bar{y}_{B_j}$ being the average of the observation $\{y_i\}$ allocated to node B_j.

2 Predictions

Consider the case we want to predict the response y_{n+1} for a future subject based on the predictors x_{n+1} and $(y_1, \ldots, y_n)$. For each tree level, the new vector of predictors x_n is allocated to subsets having closer centers with respect some metric. We will consider the euclidean metric. Then, for a new observation the predictive density is defined as

$$p(y_{n+1}|x_{n+1}, y_1, \ldots, y_n) = \int f\left(y_{n+1}|x_{n+1}, \Omega\right) dp\left(\Omega|y_1, \ldots, y_n\right) \tag{1}$$

with $f\left(y_{n+1}|x_{n+1}, \Omega\right)$ defined as in (1) and Ω being the set of all parameters involved, i.e. weights, location and scale parameters. In order to make inference on the predictive density of y_{n+1}, at the sth Gibbs sampler iteration, we will first sample parameters involved in **??** from its posterior, i.e. $\Omega^{(s)} \sim p\left(\Omega|y_1, \ldots, y_n\right)$ and then we will sample $y_{n+1}^{(s)}$ from $p\left(y_{n+1}|x_{n+1}, \Omega^{(s)}\right)$. Let us assume the number of iterations is S an a burn-in of b is considered. Then, given the sequence $\left(y_{n+1}^{(b+1)}, \ldots, y_{n+1}^{(S)}\right)$, summaries of the predictive density such as mean, variance and quantiles can be computed.

3 Partition Tree Schematic

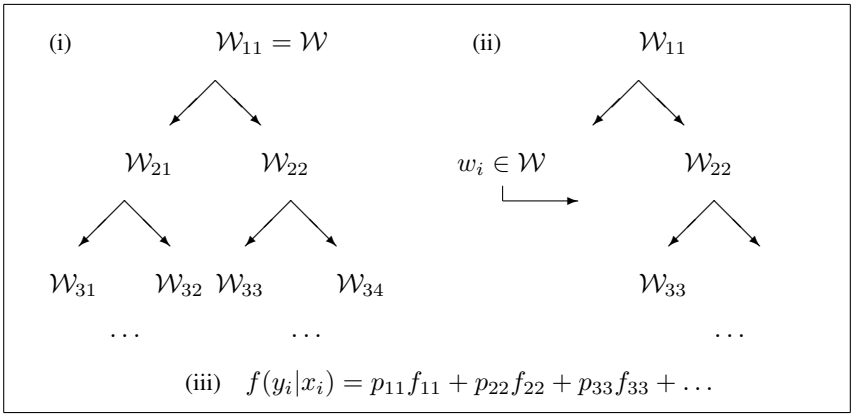

Figure 1: (i) Multiscale partition of the data. (ii) Path through the tree for $x_i \in \mathbb{R}^p$. (iii) Conditional density of y_i given x_i defined as a convex combination of densities along the path.
